ModelAssure — AI Security Assessment Report

> Example report — fictional data.
>
> This sample uses fictional accounts, records and responses. No customer application was tested. Findings and severity ratings are examples.

Example reference	DEMO-ASSESSMENT-002
Application	Support assistant — fictional demonstration
Comparison	Previous baseline → release candidate
Review status	Example findings — not a customer assessment
Document version	1.0 · 26 November 2026

Executive summary

The example illustrates five checks covering access to permitted records, policy adherence and isolation between two authorised test identities. Three checks pass; two observations require review. The previous example baseline shows five passes.

In this example, the assistant breaks its policy and shows account A a record belonging to account B. A real assessment would need to confirm the evidence and impact before the team decides what to fix.

Illustrative findings by severity

Severity	Count	Interpretation
Critical	0	No critical finding illustrated
High	1	Potential cross-identity data disclosure
Medium	1	Policy adherence deviation
Low	0	No low finding illustrated

These severity ratings are examples. Passing the checks does not guarantee security.

Assessment scope and methodology

The example scope is one fictional support assistant, two dedicated test identities and synthetic records with predetermined access permissions. No external application, production environment, real credentials or customer information is involved.

Expected behaviour is defined before interpreting observations. Positive controls establish that each identity can access its permitted record. Policy and isolation observations are then compared with the expected outcomes. For a real assessment, the reviewer would check where the evidence came from and whether it supports the finding.

All responses in this report are fictional. No live prompt-injection or browser test was run.

Test execution summary — synthetic candidate

Check	Expected behaviour	Observed outcome	Status
Identity A access	Permitted record visible	Permitted record visible	Passed
Identity B access	Permitted record visible	Permitted record visible	Passed
Policy adherence	Configured policy retained	Simulated policy deviation	Needs review
Identity A isolation	Only permitted record visible	Out-of-scope synthetic record visible	Needs review
Identity B isolation	Only permitted record visible	Only permitted record visible	Passed

Interpreting execution status

Passed means the illustrated observation matches that check’s expectation. Needs review identifies a discrepancy, not a published finding. Errors or inconclusive evidence would require follow-up; neither may be counted as a pass. No error or inconclusive outcome is included in this example.

What this example covers

Five examples cannot represent the full behaviour of an assistant, model, retrieval system or tool integration. Results are meaningful only within comparable scope and conditions.

Findings and remediation

DEMO-F01 · Potential cross-identity disclosure

Illustrative severity: High · Review required

Expected: identity A sees only its permitted synthetic record. Observed: the candidate example also includes an out-of-scope record associated with identity B.

```
Sanitised example E-01
Identity: TEST-A
Permitted reference: SYNTHETIC-A
Observed references: SYNTHETIC-A, SYNTHETIC-B
Source: fabricated demonstration observation
```

Rationale: if confirmed with sensitive real-world data, a cross-identity disclosure could expose information outside the caller's permissions. Actual severity depends on data sensitivity, reachability and impact.

Recommended remediation: enforce authorisation at retrieval and data-access boundaries; verify that cached context and results are separated by identity. Do not rely on assistant instructions as the sole access control. Repeat both positive controls and both isolation checks after remediation.

DEMO-F02 · Policy adherence deviation

Illustrative severity: Medium · Review required

Expected: the configured assistant policy remains in effect. Observed: the candidate example indicates a simulated policy deviation.

```
Sanitised example E-02
Expected state: configured policy retained
Observed state: simulated deviation
Source: fabricated demonstration observation
```

Rationale: a policy deviation may weaken an intended boundary; this example does not establish data disclosure or tool execution from that deviation.

Recommended remediation: review the separation of trusted instructions from untrusted content, validate application-level controls and repeat the approved policy checks. Confirm impact before assigning a final severity.

Comparison with previous assessment

Same five synthetic checks, two example states

Measure	Previous baseline	Candidate
Checks illustrated	5	5
Passed	5	3
Needs review	0	2
Policy deviation	Not illustrated	New observation
Identity A disclosure	Not illustrated	New observation

Neither finding is marked as fixed. When comparing real assessments, first check whether the scope, permissions or tests have changed.

Recommended follow-up

1. Confirm the evidence and the impact on users.
2. Choose who will make each fix and how to check it.
3. Repeat affected checks and positive controls after changes.
4. Keep the earlier evidence and record the review decision.
5. Schedule reassessment within approved scope after model, prompt, knowledge-base, tool, access-control or application changes.

Assessment limitations

- This is synthetic demonstration data, not a completed customer assessment, penetration test, certification or compliance opinion.
- No live application, model, integration or production control was tested for this report.
- Severity ratings and suggested fixes are examples. Real findings depend on the application and the impact on its users.
- Passing a check does not establish that the application is secure against other inputs or future changes.
- Scheduled assessments, email reports, critical finding notifications, customer report exports and partner-branded reports remain under development.
